HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Please ensure that your abstract fits into one column on one page and complies with the *Instructions to Authors* available from the Abstract Submission web page.

The role of pesticides in stabilization of TiO₂ nanoparticles in aquatic environments

The influence of pesticides (glyphosate, aminomethylphosphonic acid (AMPA) and 2.4-D) on the surface charge and aggregation of pure TiO₂ nanoparticles (NP; 5-30 nm; anatase and rutile) have been investigated in modeled water solutions. The dependence of the surface charge and the size distribution at upon the various factors (including surface chemistry of NP and pesticides, presence of mono- (Na⁺) and bi-valent (Ca²⁺) cations, pH value, and ionic strength (IS) of an aqueous solution) has been studied.

The presence of glyphosate (5 µg/L) affects rutile TiO₂ NP (5 mg/L) stabilization in NaCl solution of IS=10⁻⁴M - 10⁻³M (>CCC) and in CaCl₂ solution of IS =10⁻⁴M (>CCC) with pH=5 near the pH point of zero charge (PZC) (pH_{PZC}=4.5). With adding of the glyphosate no changes in NP aggregation were observed in very high (IS= 10⁻¹M) ionic strength solutions for rutile NP and in all studied conditions for anatase NP. No significant changes in NP aggregation were observed in the presence of AMPA and 2.4-D. Compared to mono-valent cations, bi-valent cations favored an increase in zeta potential at pH8 and no changes at pH5. These results show new evidences of the role of pesticides on the NP mobility in aquatic environments.
